

## A GENERALIZATION OF $H$ -CLOSED SPACES

C. K. BASU, M. K. GHOSH AND S. S. MANDAL

**Abstract.** Whereas a space  $X$  can be embedded in a compact space if and only if it is Tychonoff, every space  $X$  can be embedded in an  $H$ -closed space (a generalization of compact space). In this paper, we further generalize the concept of  $H$ -closedness into  $gH$ -closedness and have shown that every connected space is either a  $gH$ -closed space or can be embedded in a  $gH$ -closed space. Also, in a locally connected regular space the concept of  $gH$ -closedness is equivalent to the concepts of  $J$ -ness and strong  $J$ -ness due to E. Michael [7] and  $\theta$ -ness due to C.K. Basu et. al [1]. Several characterizations and properties of  $gH$ -closed spaces with respect to subspaces, products and functional preservations (along with various examples) are given.

### 1. Introduction

The concept of an  $H$ -set (a generalization of an  $H$ -closed space) was initiated by N. Veličko [15]. Since then  $H$ -sets played a major role in the development of the theory of  $H$ -closed spaces, locally  $H$ -closed spaces [10] although the exact relationship between  $H$ -sets and  $H$ -closed subspaces is as yet unknown. Indeed, unlike compactness,  $H$ -closure is not an absolute property.

Attempts have been made to use such  $H$ -sets in place of compact sets as is in the case of strong  $J$ -spaces due to E. Michael [7], to initiate a new class of spaces called  $gH$ -closed spaces. In what follows, attention will be focused upon  $gH$ -closed spaces because of the fact that not only every  $H$ -closed space is  $gH$ -closed (shown in section 2) but also every connected space is either a  $gH$ -closed space or can be embedded in a  $gH$ -closed space (shown in section 4). This result may make a new insight in investigating connected non  $H$ -closed (non compact as well) spaces. Several characterizations and properties of  $gH$ -closed spaces analogous to strong  $J$ -spaces due to E. Michael [7] have been achieved.

All the spaces considered herein are assumed to be Hausdorff. We assume that the reader is familiar with the concepts of  $H$ -closedness,  $H$ -sets,  $\theta$ -closed sets and  $\theta$ -continuity; [12, 16] might very well serve as the necessary background. The  $\theta$ -closure of a subset  $A$  of a space  $X$  is the set  $[A]_{\theta} \equiv \{x \in X : \overline{U} \cap A \neq \emptyset \text{ for all open sets } U \text{ containing } x\}$ . A subset  $A$  is  $\theta$ -closed if  $A = [A]_{\theta}$  and the complement of a  $\theta$ -closed set is a  $\theta$ -open set; a subset which is both  $\theta$ -open as well as  $\theta$ -closed is called  $\theta$ -clopen. The  $\theta$ -boundary [1] of a subset  $A$  of  $X$  ( $\theta$ -bd  $A$ , for short) is defined as  $[A]_{\theta} \cap [X - A]_{\theta}$ .

2000 *Mathematics Subject Classification.* 54D20, 54D25, 54D99.

*Key words and phrases.*  $H$ -closed,  $H$ -set,  $\theta$ -closed,  $\theta$ -continuity,  $\theta$ -connected,  $\theta$ -perfect, almost regular, Urysohn,  $\theta$ -rigid.

The other concepts needed for investigation of  $gH$ -closed spaces are: almost regularity,  $\theta$ -connectedness,  $\theta$ -rigidity and  $\theta$ -perfectness. A space  $(X, \tau)$  is said to be almost regular [13, 8] iff  $\tau_s = \tau_\theta$  (where  $\tau_s, \tau_\theta$  are respectively the semi-regularization topology and the  $\theta$ -topology). Every regular space is almost regular but not conversely. A pair  $(P, Q)$  of non-empty subsets of  $X$  is called a  $\theta$ -separation relative to  $X$  iff  $(P \cap [Q]_\theta) \cup (Q \cap [P]_\theta) = \emptyset$ ; a subset  $A$  is called  $\theta$ -connected [2] iff  $A$  is not the union of  $P$  and  $Q$  where  $(P, Q)$  is a  $\theta$ -separation relative to  $X$ . Clearly every connected set is  $\theta$ -connected but the converse is not true and in a regular space these two concepts coincide. A subset  $A$  of  $X$  is  $\theta$ -rigid [3] iff for each open cover  $\mathcal{U}$  of  $A$ , there is a finite subfamily  $\{U_1, U_2, \dots, U_n\}$  of  $\mathcal{U}$  such that  $A \subseteq \text{int}(\bigcup_{i=1}^n U_i)$ ; in a Hausdorff space, every  $\theta$ -rigid set is an  $H$ -set [3]. A filter  $\mathcal{F}$  in  $X$  almost converges [3] to a subset  $A$  (written  $\mathcal{F} \hookrightarrow A$ ) if for each open cover  $\mathcal{A}$  of  $A$ , there is a finite subfamily  $\mathcal{B} \subseteq \mathcal{A}$  such that  $\cup\{cIV : V \in \mathcal{B}\} \in \mathcal{F}$ . A function  $f : X \rightarrow Y$  is  $\theta$ -perfect [3] iff for every filter base  $\mathcal{F}$  on  $f(X)$ ,  $\mathcal{F} \hookrightarrow y$  implies  $f^{-1}(\mathcal{F}) \hookrightarrow f^{-1}(y)$ .

Some results from literature are cited below:

- #1.1. If  $f : X \rightarrow Y$  is  $\theta$ -continuous surjective and  $X$  is  $H$ -closed then  $Y$  is  $H$ -closed [16].
- #1.2. If  $f : X \rightarrow Y$  is  $\theta$ -continuous, when  $A \subset X$  is an  $H$ -set, then  $f(A)$  is an  $H$ -set in  $Y$  [16].
- #1.3. An almost regular  $T_2$  space is Urysohn [13].
- #1.4. An  $H$ -set in a Urysohn space is  $\theta$ -closed [14].
- #1.5. Let  $f : X \rightarrow Y$  be a function, where  $X$  and  $Y$  are almost regular spaces. Then  $f$  is  $\theta$ -continuous iff inverse image of every  $\theta$ -open (resp.  $\theta$ -closed) set of  $Y$  is  $\theta$ -open (resp.  $\theta$ -closed) in  $X$  [5].
- #1.6. A  $\theta$ -closed subset of an  $H$ -closed space is an  $H$ -set [3].
- #1.7. A space  $X$  is  $H$ -closed iff for every space  $Y$ , the projection map from  $X \times Y$  onto  $Y$  takes a  $\theta$ -closed subset onto a  $\theta$ -closed subset [6].
- #1.8. If  $A \subset X$  is an  $H$ -set of  $X$  and  $X \subset Y$ , then  $A$  is an  $H$ -set in  $Y$  [16].
- #1.9. Let  $B$  be a regular closed subset of a  $T_2$  space  $X$ . If  $A \subset X$  is an  $H$ -set and  $B \subset A$  then  $B$  is  $H$ -closed [16].
- #1.10. For any subset  $A \subset X$ ,  $[A]_\theta$  is  $\theta$ -closed if  $X$  is almost regular [5].
- #1.11. In an almost regular space  $X$ , every regular closed (resp. every regular open) subset is  $\theta$ -closed (resp.  $\theta$ -open) [5].
- #1.12. If  $f : X \rightarrow Y$  is  $\theta$ -continuous, the mapping  $f : X \rightarrow f(X)$  need not be  $\theta$ -continuous (even if  $f(X)$  is a regular subspace of  $Y$ ) [15].
- #1.13. If  $f : X \rightarrow Y$  is  $\theta$ -continuous and  $f(X) \subset Z \subset Y$  and  $Z$  is dense in  $Y$ , then  $f : X \rightarrow Z$  is  $\theta$ -continuous [16].
- #1.14. If  $f : X \rightarrow Y$  is  $\theta$ -continuous and  $A \subset X$ , then  $f/A : A \rightarrow Y$  is  $\theta$ -continuous [16].
- #1.15. If  $Y$  is an  $H$ -set in  $X$  and  $A$  is a  $\theta$ -closed subset of  $X$  then  $A$  is an  $H$ -set if  $A \subset Y$  [14].
- #1.16. If  $A \subset Y \subset X$ ,  $A$  is  $\theta$ -open in  $Y$  and  $Y$  is  $\theta$ -open in  $X$ , then  $A$  is  $\theta$ -open in  $X$  [14].
- #1.17. If  $A \subset Y \subset X$  and  $Y$  is  $\theta$ -open in  $X$ ;  $A$  is  $\theta$ -closed in  $Y$ , then  $A = F \cap Y$ , where  $F$  is  $\theta$ -closed in  $X$  [14].
- #1.18. Let  $Y$  be an open subset of  $X$  and  $X$  be almost regular; then  $Y$  is almost regular [5].
- #1.19. In an  $H$ -closed Urysohn space, every  $H$ -set is  $\theta$ -closed and every  $\theta$ -closed set is an  $H$ -set [3].

#1.20. Let  $f : X \rightarrow Y$  be a  $\theta$ -continuous  $\theta$ -bd perfect map from an almost regular space  $X$  onto a Urysohn space  $Y$ . If  $X$  is a  $\theta J$ -space then so is  $Y$  [1].

## 2. $gH$ -closed spaces.

**Definition 2.1.** A space  $X$  is called a generalized  $H$ -closed space ( $gH$ -closed, for short) if for every  $H$ -set  $H$  of  $X$ , there is an  $H$ -set  $K$  in  $X$  such that  $H \subset K$  and  $X - K$  is  $\theta$ -connected relative to  $X$ .

**Remark 2.2.** Every  $H$ -closed space is a  $gH$ -closed space. But the converse is not true.

### Examples of $gH$ -closed spaces that are not $H$ -closed.

**Example 2.3.** On  $R^+ = [0, \infty)$ , let us consider  $\tau$ , the countable complement extension topology of the usual topology  $\mathcal{U}$  on  $R^+ = [0, \infty)$ . Then as  $\tau_s = \tau_\theta = \mathcal{U}$ , the space  $(R^+, \tau)$  is almost regular and Hausdorff. It can be checked that this space is non-regular, non  $H$ -closed and non locally connected. In this space  $(R^+, \tau)$ , let  $H$  be an  $H$ -set and hence  $H$  is compact in  $(R^+, \mathcal{U})$ . Therefore,  $h = \sup H$  exists. Obviously,  $H \subset [0, h]$  and  $R^+ - [0, h] = (h, \infty)$  is connected in  $(R^+, \mathcal{U})$ . As  $(h, \infty)$  is  $\theta$ -open in  $(R^+, \tau)$  and is connected in  $(R^+, \tau_\theta)$ , by proposition 3 [8],  $(h, \infty)$  is  $\theta$ -connected relative to  $(R^+, \tau)$ . Clearly  $[0, h]$  is an  $H$ -set in  $(R^+, \tau)$ . Hence  $(R^+, \tau)$  is a  $gH$ -closed space.

**Example 2.4.** Let  $\tau$  be the countable complement extension topology of the real line  $(R, \mathcal{U})$ . Then as  $\tau_s = \tau_\theta = \mathcal{U}$ , the space  $(R, \tau)$  is almost regular. Easy verification shows that this space is connected but not  $H$ -closed; also  $(R, \tau)$  is not  $gH$ -closed because of the Theorem 2.16 (given latter) and it is not  $\theta J$  [Example 2.4, 1]. Therefore, by Theorem 4.1 (given latter),  $(R^n, \tau^n)$ ,  $n > 1$  is a  $gH$ -closed space. Obviously  $(R^n, \tau^n)$  is not  $H$ -closed; otherwise,  $(R, \tau)$  would be  $H$ -closed — a contradiction.

**Lemma 2.5 [1].** If  $Y \subset X$  and  $B$  is  $\theta$ -closed ( $\theta$ -open) in  $(X, \tau)$  then  $B \cap Y$  is  $\theta$ -closed ( $\theta$ -open) in  $(Y, \tau_Y)$ , where  $\tau_Y$  is the subspace topology on  $Y$ .

**Lemma 2.6 [14].** If  $A \subset Y \subset X$ , and  $A$  is  $\theta$ -open in  $Y$  and  $Y$  is a  $\theta$ -open in  $X$  then  $A$  is  $\theta$ -open in  $X$ .

But for  $\theta$ -closed sets, the lemma 2.6 does not hold.

**Example 2.7.([1])** Let  $\tau$  be the countable complement extension topology of the real line  $(R, \mathcal{U})$ . Now, let  $Y = \{0, 1, \frac{1}{2}, \frac{1}{3}, \dots\}$ , obviously  $\{0\}$  is open and closed in  $(Y, \tau_Y)$  and  $Y$  is  $\theta$ -closed in  $(R, \tau)$  as  $Y$  is closed in  $(R, \mathcal{U})$ . Hence  $\overline{\{0\}} \cap \{1, \frac{1}{2}, \frac{1}{3}, \dots\} = \emptyset$ , implying that  $A = \{1, \frac{1}{2}, \frac{1}{3}, \dots\}$  is  $\theta$ -closed in  $(Y, \tau_Y)$  (where the closure is taken in the subspace topology) but  $A$  is not  $\theta$ -closed in  $(R, \tau)$ , since  $A$  is not closed in  $(R, \mathcal{U})$ .

**Lemma 2.8.([1])** A subset  $H$  of an almost regular space  $X$  is an  $H$ -set, iff every  $\theta$ -open cover of  $A$  has a finite subcover.

It is well known that every  $H$ -closed subspace is an  $H$ -set but example exists in [15], which shows that the converse is not true in general. Now we give the following characterization theorem for  $gH$ -closed spaces.

**Theorem 2.9.** *Let  $\{H_1, H_2\}$  be a  $\theta$ -clopen cover of an almost regular space  $X$ , with  $H_1 \cap H_2$  an  $H$ -set. Then the following are equivalent:*

- (i)  $X$  is  $gH$ -closed.
- (ii)  $H_1$  and  $H_2$  are  $gH$ -closed, and  $H_1$  or  $H_2$  is an  $H$ -set.

**Proof.** (i) $\Rightarrow$ (ii) Let  $H_1$  be an  $H$ -set. Then obviously  $H_1$  is regular closed and hence  $H_1$  is an  $H$ -closed subspace of  $X$  (by result 1.9). Therefore, by Remark 2.2,  $H_1$  is a  $gH$ -closed subspace of  $X$ . To show  $H_2$  is a  $gH$ -closed subspace of  $X$ , let  $K_2 \subset H_2$  be an  $H$ -set in the subspace  $H_2$ . Then, by result 1.8,  $K_2$  is an  $H$ -set in  $X$ . So,  $H = K_2 \cup H_1$  is an  $H$ -set in  $X$ . Since  $X$  is  $gH$ -closed, there exists some  $H$ -set  $L$  in  $X$  with  $H \subset L$  and  $X - L$  is  $\theta$ -connected. Let  $L_2 = L \cap H_2$ . Then  $K_2 \subset L_2$  and  $L_2$  is not only a  $\theta$ -closed set in  $H_2$  but also in  $X$  (by result 1.3 and 1.4). In addition,  $L_2 \subset H_2$  is an  $H$ -set in  $X$  (by result 1.15). Since  $H_2$  is  $\theta$ -open and hence is almost regular (by result 1.18), then by lemma 2.8, it can be easily shown that  $L_2$  is an  $H$ -set in subspace  $H_2$ . Since  $H_2 - L_2 = X - L$  then  $H_2 - L_2$  is  $\theta$ -connected in  $X$ . Again as  $H_2$  is  $\theta$ -open,  $H_2 - L_2$  is  $\theta$ -connected in the subspace  $H_2$ . Therefore,  $H_2$  is a  $gH$ -closed space.

(ii) $\Rightarrow$ (i) Suppose (ii) holds and also suppose  $H_1$  be an  $H$ -set. Let  $H \subset X$  be an  $H$ -set. Then  $K = (H \cup H_1) \cap H_2$  is an  $H$ -set in  $X$  such that  $K \subset H_2$ . Since  $H_2$  is  $\theta$ -open, by lemma 2.8 and results 1.16, 1.18, we can easily prove that  $K$  is an  $H$ -set in  $H_2$ . The  $gH$ -closedness of the subspace  $H_2$  implies that there exists some  $H$ -set  $L$  in the subspace  $H_2$  such that  $K \subset L$  and  $H_2 - L$  is  $\theta$ -connected in  $H_2$ . The set  $L^* = L \cup H_1$  is an  $H$ -set containing  $H$  and one can check that  $X - L^* = H_2 - L$  is  $\theta$ -connected in  $X$ . Therefore  $X$  is a  $gH$ -closed space.

**Corollary 2.10.** *If  $A$  is a  $\theta$ -clopen subset of an almost regular  $gH$ -closed space  $X$  then  $A$  is a  $gH$ -closed space.*

**Remark 2.11.** (a) In [1] we considered a kind of spaces termed  $\theta$ -J spaces (see Definition 2.15) which satisfy a condition weaker than that given in (ii) of Theorem 2.9. Indeed, we shall show shortly (see Theorem 2.16) that every  $gH$ -closed space is a  $\theta$ -J space for which we need not assume the condition of almost regularity on the underlying space.

(b) The condition in the above corollary is not necessary. In the space  $(R^+, \tau)$  in Example 2.3,  $Y = [0, 1]$  with the subspace topology  $\tau_Y$  is  $H$ -closed and hence is a  $gH$ -closed subspace. Although  $Y$  is  $\theta$ -closed in  $(R^+, \tau)$  but because of the fact that  $Y$  is not open in  $(R^+, \mathcal{U})$ , it is not  $\theta$ -open in  $(R^+, \tau)$ .

On the otherhand, union of even two  $\theta$ -closed  $gH$ -closed subspaces may not be  $gH$ -closed. In Example 2.4,  $R^+ = \{x \in R : x \geq 0\}$  and  $R^- = \{x \in X : x \leq 0\}$  are both  $\theta$ -closed  $gH$ -closed subspaces but their union  $(R, \tau)$  is not so. But we have the following corollary.

**Corollary 2.12.** *If an almost regular space  $X$  be such that  $X = H_1 \cup H_2$  with  $H_1$  an open  $gH$ -closed subspace,  $H_2$  a  $\theta$ -clopen  $H$ -set, then  $X$  is a  $gH$ -closed space.*

**Proof.** Let  $A = X - H_2$ . Then  $A$  is  $\theta$ -clopen subset in the subspace  $H_1$ . By result 1.18  $H_1$  is almost regular (being an open subspace of an almost regular space  $X$ ) and as  $H_1$  is a  $gH$ -closed space, the Corollary 2.10 implies  $A$  is a  $gH$ -closed subspace. Again  $H_2$  is being a regular closed  $H$ -set in  $X$ , by result 1.9,  $H_2$  is an  $H$ -closed subspace of  $X$  and hence is a  $gH$ -closed subspace in  $X$  (by Remark 2.2). Since  $\{A, H_2\}$  is a  $\theta$ -clopen cover of  $X$ ,  $A$  and  $H_2$  are  $gH$ -closed subspaces and  $H_2$  is an  $H$ -set, by Theorem 2.9,  $X$  is a  $gH$ -closed space.

**Theorem 2.13.** Let  $X$  be an almost regular  $gH$ -closed space. Then every regular closed set  $B$  which is a union of  $\theta$ -components of  $X$  [2] is  $gH$ -closed.

**Proof.** Let  $A \subset B$  be an  $H$ -set in the subspace  $B$ . Then by result 1.8,  $A$  is an  $H$ -set in  $X$  and hence the  $gH$ -closedness of  $X$  implies the existence of an  $H$ -set  $H$  (in  $X$ ) such that  $A \subset H$  and  $X - H$  is  $\theta$ -connected relative to  $X$ . Now, if  $B \subset H$ , then because of  $X$  is almost regular,  $B$  is a  $\theta$ -closed set (by result 1.11) contained in an  $H$ -set  $H$  and hence (by result 1.15)  $B$  is an  $H$ -set. In fact,  $B$  is a  $H$ -closed subspace of  $X$  (by result 1.9). So, by Remark 2.2,  $B$  is  $gH$ -closed. If  $B \not\subset H$ , then the  $\theta$ -connected set  $X - H$  intersects  $B$ ; but as  $B$  is a union of  $\theta$ -components of  $X$ , the only possibility is  $X - H \subset B$ . Let  $H_1 = H \cap B$ . Using results 1.3, 1.4 and 1.15, it can be shown that  $H_1$  is an  $H$ -set in  $X$ . Obviously  $A \subset H_1$  and also  $B - H_1 = X - H$  is  $\theta$ -connected relative to  $X$ . Since  $X - H$  is a  $\theta$ -open set (in  $X$ ) contained in  $B$ , then by lemma 2.5,  $X - H$  is  $\theta$ -open in the subspace  $B$ . If  $(P, Q)$  is any  $\theta$ -separation of the  $\theta$ -open set  $X - H$  in the subspace  $B$ , such that  $X - H = P \cup Q$  then by [8, Proposition 1],  $P, Q$  are  $\theta$ -open sets in  $B$ . Since the  $\theta$ -closure and the closure of an open set are equal and  $B$  is closed in  $X$ ,  $(P, Q)$  is therefore a separation of the connected set  $X - H$  (because an open subset of  $(X, \tau)$  is connected iff it is  $\theta$ -connected relative to  $X$  [8, Proposition 2]) — a contradiction. So,  $B - H_1 = X - H$  is  $\theta$ -connected in the subspace  $B$  and hence  $B$  is a  $gH$ -closed subspace of  $X$ .

**Corollary 2.14.** Every regular closed subset which is a union of  $\theta$ -components of an almost regular  $H$ -closed space is  $gH$ -closed.

**Definition 2.15.** A space  $X$  is a  $\theta J$ -space [1] if whenever  $\{H_1, H_2\}$  is a  $\theta$ -closed cover of  $X$  with  $H_1 \cap H_2$  an  $H$ -set,  $H_1$  or  $H_2$  is an  $H$ -set.

**Theorem 2.16.** Every  $gH$ -closed space is a  $\theta J$ -space.

**Proof.** Suppose  $(X, \tau)$  is a  $gH$ -closed space. Let  $\{H_1, H_2\}$  be a  $\theta$ -closed cover of  $X$  with  $H_1 \cap H_2$  an  $H$ -set. As  $(X, \tau)$  is  $gH$ -closed and  $H_1 \cap H_2 \subset X$  is an  $H$ -set, so  $H_1 \cap H_2 \subset K$  for some  $H$ -set  $K$  of  $(X, \tau)$  with  $X - K$   $\theta$ -connected. By lemma 2.5,  $(H_1 \cap (X - K), H_2 \cap (X - K))$  is a disjoint  $\theta$ -closed cover of the  $\theta$ -connected set  $X - K$ . So, either  $H_1 \cap (X - K) = \emptyset$  or  $H_2 \cap (X - K) = \emptyset$  implying either  $H_1 \subset K$  or  $H_2 \subset K$ . But  $H_1$  or  $H_2$  is a  $\theta$ -closed subset contained in an  $H$ -set  $K$ . So, by result 1.15, either  $H_1$  or  $H_2$  is an  $H$ -set. Therefore  $(X, \tau)$  is a  $\theta J$ -space.

We shall show that in a locally connected almost regular space, these two concepts are equivalent. For this we first state a theorem.

**Theorem 2.17.** ([1]) An almost regular space  $X$  is a  $\theta J$ -space iff whenever  $H \subset X$  is an  $H$ -set and  $\mathcal{U}$  is a disjoint  $\theta$ -open cover of  $X - H$ , then  $X - U$  is an  $H$ -set for some  $U \in \mathcal{U}$ .

In view of the following proposition due to Mršević et al i.e.

**Proposition 2.18.** ([8]) *In  $(X, \tau)$ , the conditions (i) — (iii) below are equivalent: every point has a neighbourhood basis in  $(X, \tau)$  consisting of:*

- (i) *connected neighbourhoods.*
- (ii)  *$\delta$ -connected neighbourhoods.*
- (iii) *neighbourhoods  $\theta$ -connected relative to  $X$ .*

We have the following theorem:

**Theorem 2.19.** *A locally connected almost regular space is a  $\theta$ J-space iff it is a  $gH$ -closed space.*

**Proof.** Every  $gH$ -closed space is a  $\theta$ J-space (by Theorem 2.16).

Let  $X$  be a locally connected  $\theta$ J-space and  $H \subset X$  be an  $H$ -set. As  $X$  is almost regular  $T_2$ ,  $X$  is not only a Urysohn space but also every  $H$ -set of  $X$  is  $\theta$ -closed; further for any open neighbourhood  $U$  of  $x$  there exists a  $\theta$ -open set  $V$  of  $x$  such that  $V \subset \overline{U}$ . Indeed, by definition of almost regularity, there exists, an open set  $W$  such that  $x \in W \subset \overline{W} \subset \text{int}\overline{U} \subset \overline{U}$ ; but in the almost regular space  $X$ , the regular open set  $V = \text{int}\overline{U}$  is  $\theta$ -open. Because of  $X$  is locally connected Urysohn and  $H$  is  $\theta$  closed in  $X$ , it can be easily shown that, there is a disjoint  $\theta$ -open cover  $\mathcal{U}$  of  $X - H$  with each  $U \in \mathcal{U}$   $\theta$ -connected. Since  $X$  is  $\theta$ J-space by Theorem 2.17, there exists a  $U^* \in \mathcal{U}$  such that  $X - U^*$  is an  $H$ -set. If we take  $K = X - U^*$ , then  $H \subset K$  and  $X - K = U^*$  is  $\theta$ -connected. So,  $X$  is a  $gH$ -closed space.

### 3. Preservation of $gH$ -closedness in terms of $\theta$ -perfect ( $\theta$ -bd perfect) functions.

**Definition 3.1.** ([1]) A map  $f : X \rightarrow Y$  is called  $\theta$ -boundary perfect ( $\theta$ -bd perfect, for short) if  $f$  is almost closed [3] (i.e.  $f([A]_\theta) = [f(A)]_\theta, \forall A \subset X$ ) and  $\theta$ -bd  $f^{-1}(y)$  is  $\theta$ -rigid [3] for every  $y \in Y$ .

**Theorem 3.2.** *For an almost regular space  $X$  if*

- (i)  *$X$  is  $gH$ -closed space then*
- (ii) *every  $\theta$ -continuous  $\theta$ -bd perfect map  $f : X \rightarrow Y$  onto a non  $H$ -closed Urysohn space  $Y$  is  $\theta$ -perfect.*

**Proof.** Let  $f : X \rightarrow Y$  be a  $\theta$ -continuous  $\theta$ -bd perfect map and let  $y \in Y$ . Since  $\theta$ -bd  $f^{-1}(y)$  is a  $\theta$ -rigid set and hence is an  $H$ -set (by remark after Corollary 6.3, [3]), then as  $X$  is a  $gH$ -closed space there exist an  $H$ -set  $K$  such that  $[f^{-1}(y)]_\theta \cap [X - f^{-1}(y)]_\theta = \theta$ -bd  $f^{-1}(y) \subset K$  and  $X - K$  is  $\theta$ -connected. But  $\{[f^{-1}(y)]_\theta \cap (X - K), [X - f^{-1}(y)]_\theta \cap (X - K)\}$  is a  $\theta$ -separation of  $(X - K)$ . So, either  $[f^{-1}(y)]_\theta \subset K$  or  $[X - f^{-1}(y)]_\theta \subset K$ . But, by results 1.10 and 1.15, either  $[f^{-1}(y)]_\theta$  or  $[X - f^{-1}(y)]_\theta$  is an  $H$ -set. Now as  $f$  is  $\theta$ -continuous and  $\{y\}$  is a  $\theta$ -closed set being an  $H$ -set in the Urysohn space  $Y$  (by result 1.4),  $f^{-1}(y)$  is  $\theta$ -closed i.e.  $f^{-1}(y) = [f^{-1}(y)]_\theta$ . Since  $[X - f^{-1}(y)]_\theta$  is a non- $H$ -set otherwise  $Y$  would be  $H$ -closed, so by Theorem 3.4 [3],  $f$  is  $\theta$ -perfect.

**Remark 3.3.** If  $Y$  is  $H$ -closed then the above theorem fails. In fact, if  $f : X \rightarrow Y$ , where  $Y$  is a singleton and  $X$  is  $gH$ -closed but not  $H$ -closed then  $f$  is a  $\theta$ -continuous  $\theta$ -bd perfect map onto a Urysohn space  $Y$ . But  $f$  is not  $\theta$ -perfect as  $f^{-1}(y)$  is not a  $\theta$ -rigid set.

**Theorem 3.4.** Let  $f : X \rightarrow Y$  be a  $\theta$ -continuous,  $\theta$ -bd perfect  $\theta$ -open map (i.e. maps  $\theta$ -open sets into  $\theta$ -open sets) from an almost regular space  $X$  onto a Urysohn space  $Y$ . Then  $Y$  is a  $gH$ -closed space if  $X$  is so.

**Proof.** If  $Y$  is  $H$ -closed then by Remark 2.2,  $Y$  is  $gH$ -closed. Suppose  $Y$  is not an  $H$ -closed space. Then by above Theorem 3.2,  $f$  is  $\theta$ -perfect. Let  $H \subset Y$  be an  $H$ -set then  $H_1 = f^{-1}(H) \subset X$  is an  $H$ -set, by Corollary 3.1.1.(c) [3]; but the  $gH$ -closedness of  $X$  implies the existence of an  $H$ -set  $K_1 \subset X$  such that  $H_1 \subset K_1$  and  $X - K_1$  is  $\theta$ -connected. Since  $f$  is  $\theta$ -continuous, by Theorem 2.7 [2],  $f(X - K_1)$  is  $\theta$ -connected. Obviously,  $H_2 = Y - f(X - K_1)$  is  $\theta$ -closed and  $f$  being  $\theta$ -continuous, the  $\theta$ -closed set  $f^{-1}(H_2) \subset K_1$  is an  $H$ -set in  $X$  by result 1.15. Since  $f$  is  $\theta$ -continuous, by result 1.2,  $H_2$  is an  $H$ -set in  $Y$  such that  $H \subset H_2$ . But  $Y - H_2 = f(X - K_1)$  is  $\theta$ -connected. So,  $Y$  is a  $gH$ -closed space.

**Theorem 3.5.** Let  $f : X \rightarrow Y$  (where  $X$  and  $Y$  are almost regular spaces) be a  $\theta$ -continuous,  $\theta$ -perfect map onto  $Y$ . Then, if  $Y$  is a  $gH$ -closed space, so is  $X$ .

**Proof.** Let  $Y$  be  $gH$ -closed and let  $H \subset X$  be an  $H$ -set in  $X$ . Since  $f$  is  $\theta$ -continuous, by result 1.2,  $f(H) \subset Y$  is an  $H$ -set. Because of  $gH$ -closedness of  $Y$ , there is an  $H$ -set  $K$  in  $Y$  such that  $f(H) \subset K$  with  $Y - K$   $\theta$ -connected. Hence  $H \subset f^{-1}(K)$  and since  $f$  is  $\theta$ -perfect, by Corollary 3.1.1(c) [3],  $f^{-1}(K)$  is an  $H$ -set in  $X$ . We shall show that  $X - f^{-1}(K) = f^{-1}(Y - K)$  is  $\theta$ -connected. If,  $\{B_1, B_2\}$  is a  $\theta$ -separation relative to  $X$  of the  $\theta$ -open set  $f^{-1}(Y - K)$  (since  $f$  is  $\theta$ -continuous and  $Y - K$  is  $\theta$ -open such that  $f^{-1}(Y - K) = B_1 \cup B_2$ ). Then by proposition 1 [8],  $B_1$  and  $B_2$  are disjoint  $\theta$ -open sets in  $X$ . Since  $f$  is  $\theta$ -perfect, by Corollary 3.1.1(b) [3], for each  $\theta$ -closed set  $A$  of  $X$ ,  $f(A)$  is  $\theta$ -closed. From this, one can easily verify that the sets  $V_i = \{y \in Y - K : f^{-1}(y) \subset B_i\}$  for  $i = 1, 2$  are disjoint  $\theta$ -open sets. Therefore,  $Y - K$ , is not  $\theta$ -connected — a contradiction. So,  $f^{-1}(Y - K)$  is  $\theta$ -connected i.e.  $X - f^{-1}(K)$  is  $\theta$ -connected. Hence  $X$  is a  $gH$ -closed space.

**Corollary 3.6.** An almost regular space  $(X, \tau)$  is  $gH$ -closed iff  $(X, \tau_s)$  is  $gH$ -closed.

**Proof.** Since the  $\theta$ -closure of a subset  $A$  in  $(X, \tau)$  is the same as the  $\theta$ -closure of  $A$  in  $(X, \tau_s)$ , the identity map  $i_1 : (X, \tau_s) \rightarrow (X, \tau)$  is  $\theta$ -continuous and almost closed; also point inverses are  $\theta$ -rigid sets. Hence by Theorem 3.4 [4], the identity map  $i_1 : (X, \tau_s) \rightarrow (X, \tau)$  is  $\theta$ -perfect. So, if  $(X, \tau)$  is  $gH$ -closed then by above Theorem 3.5,  $(X, \tau_s)$  is  $gH$ -closed. On the otherhand, by the same reason, the identity map  $i_2 : (X, \tau) \rightarrow (X, \tau_s)$  is  $\theta$ -perfect and  $\theta$ -continuous. So, if  $(X, \tau_s)$  is  $gH$ -closed then by Theorem 3.5,  $(X, \tau)$  is  $gH$ -closed.

**Theorem 3.7.** For an almost regular locally connected space  $(X, \tau)$ , the following are equivalent:

- (i)  $(X, \tau)$  is  $gH$ -closed.
- (ii)  $(X, \tau_s)$  is  $gH$ -closed.

- (iii)  $(X, \tau_\theta)$  is  $gH$ -closed.
- (iv)  $(X, \tau)$  is  $\theta J$ .
- (v)  $(X, \tau_s)$  is  $\theta J$ .
- (vi)  $(X, \tau_\theta)$  is  $\theta J$ .

**Proof.** The proof follows from Corollary 3.6, Theorem 2.19 and from the fact that a space  $(X, \tau)$  is almost regular iff  $\tau_s = \tau_\theta$ .

**Definition 3.8.** A space  $(X, \tau)$  is a  $J$ -space (resp. strong  $J$ -space) [7] if, whenever  $\{A, B\}$  is a closed cover of  $X$  with  $A \cap B$  compact, then  $A$  or  $B$  is compact (resp. if every compact set  $K \subset X$  is contained in a compact set  $L \subset X$  with  $X - L$  connected).

**Theorem 3.9.** For a regular locally connected space  $(X, \tau)$  the following are equivalent:

- (i)  $(X, \tau)$  is  $gH$ -closed.
- (ii)  $(X, \tau)$  is  $J$ .
- (iii)  $(X, \tau)$  is  $\theta J$ .
- (iv)  $(X, \tau)$  strong  $J$ .

#### 4. $gH$ -closedness in products.

**Theorem 4.1.** If  $X_1, X_2$  are connected and non- $H$ -closed spaces then  $X_1 \times X_2$  is a  $gH$ -closed space.

**Proof.** Let  $H$  be an  $H$ -set in the product space  $X = X_1 \times X_2$  and let  $\pi_i : X \rightarrow X_i, i = 1, 2$  are projection maps. Since  $\pi_i$ 's are continuous and hence are  $\theta$ -continuous then by result 1.2,  $\pi_i(H) = H_i, i = 1, 2$  are  $H$ -sets in  $X_i, i = 1, 2$  respectively. Obviously  $H \subset H_1 \times H_2$ , where  $H_1 \times H_2$  is an  $H$ -set, by result [12, Theorem 4.8L].

But  $X_i - H_i \neq \emptyset, i = 1, 2$  otherwise  $X_i$ 's,  $i = 1, 2$  would have been  $H$ -closed. Let  $x_i \in X_i - H_i, i = 1, 2$ . Now the set  $B = (\{x_1\} \times X_2) \cup (X_1 \times \{x_2\})$  being a union of two intersecting connected and hence  $\theta$ -connected sets is  $\theta$ -connected and also  $B \subset X - (H_1 \times H_2)$ . But  $X - (H_1 \times H_2)$  is the union of  $\theta$ -connected sets of the form  $\{x_1\} \times X_2$  with  $x_1 \in X_1$  or  $X_1 \times \{x_2\}$  with  $x_2 \in X_2$  and all of which intersects  $B$  is thus  $\theta$ -connected. Therefore,  $X_1 \times X_2$  is a  $gH$ -closed space.

**Corollary 4.2.** Any connected space is either a  $gH$ -closed space or can be embedded in a  $gH$ -closed space.

**Proof.** Let  $X$  be a connected space. If it is  $H$ -closed then by Remark 2.2,  $X$  is  $gH$ -closed. If  $X$  is not an  $H$ -closed space, then by Theorem 4.1,  $X \times X$  is a  $gH$ -closed space. But as  $X$  is homeomorphic to some subspace of  $X \times X$ , the proof follows immediately.

**Corollary 4.3.**  $R^n, n > 1$ , where  $R$  is the real line with the usual topology is a  $gH$ -closed space.

**Example 4.4.** Example of a  $gH$ -closed space which is not an  $H$ -closed space.

Let  $(R, \mathcal{U})$  be the real line with usual topology. Then by above Corollary 4.3,  $R^n$ ,  $n > 1$  is a  $gH$ -closed space. But  $R^n$  is not an  $H$ -closed space.

**Theorem 4.5.** *The following are equivalent for any locally connected almost regular space  $X$ .*

- (a)  $X$  is a  $gH$ -closed space.
- (b)  $X \times Y$  is a  $gH$ -closed space for every connected  $H$ -closed almost regular space  $Y$ .
- (c)  $X \times Y$  is a  $gH$ -closed space for some  $H$ -closed almost regular space  $Y$ .

**Proof.** For proving (a) $\Rightarrow$ (b) and (b) $\Rightarrow$ (c), the assumption of local connectedness of  $X$  is not needed. Let us prove:

(a) $\Rightarrow$ (b). Let  $p_X : X \times Y \rightarrow X$  be the projection map. Now,  $p_X^{-1}(x) = \{x\} \times Y$  is an  $H$ -set in the almost regular space  $X \times Y$  (as the product of any family of almost regular space is almost regular [3, Theorem 5.1]) and therefore is a  $\theta$ -rigid set in  $X \times Y$ , by Theorem 6.4 [3]. We shall next show that for each  $A \subset X \times Y$ ,  $[p_X(A)]_\theta \subset p_X([A]_\theta)$ . For this, we first show for each  $\theta$ -closed set  $B$  of  $X \times Y$ ,  $p_X(B)$  is  $\theta$ -closed. Indeed, if  $x' \in X - p_X(B)$ ; then  $(\{x'\} \times Y) \cap B = \emptyset$ . Therefore, for each point  $(x', y)$ , has a open neighbourhood  $V_y(x') \times V(y)$  such that  $(\overline{V_y(x')} \times \overline{V(y)}) \cap B = \emptyset$ . Since  $\{x'\} \times Y$  is an  $H$ -set we can select  $V_{y_i}(x') \times V(y_i)$ ,  $i = 1, 2, \dots, n$  such that the union of the closures of such subfamily covers  $\{x'\} \times Y$ . Then  $\bigcap_{i=1}^n V_{y_i}(x')$  is a open neighbourhood of  $x'$  in  $X$  such that  $\bigcap_{i=1}^n V_{y_i}(x') \cap p_X(B) = \emptyset$ . Therefore,  $p_X(B)$  is  $\theta$ -closed.

Now,  $A \subset X \times Y$ ,  $[A]_\theta$  is  $\theta$ -closed in  $X \times Y$  (by result 1.10) and hence  $p_X([A]_\theta)$  is  $\theta$ -closed. But we always have  $p_X(A) \subset p_X([A]_\theta)$ . So  $[p_X(A)]_\theta \subset p_X([A]_\theta)$ . Therefore by Corollary 3.4.1 [3],  $p_X$  is  $\theta$ -perfect. Since  $p_X$  is continuous and hence is  $\theta$ -continuous, by Theorem 3.5,  $X \times Y$  is  $gH$ -closed.

(b) $\Rightarrow$ (c) is obvious.

(c) $\Rightarrow$ (a) If  $X$  is  $H$ -closed then by Remark 2.2,  $X$  is  $gH$ -closed. Suppose  $X$  is non  $H$ -closed then for the projection map  $p_X : X \times Y \rightarrow X$  (where  $Y$  is some  $H$ -closed space), we have  $[p_X(A)]_\theta \subset p_X([A]_\theta)$  for every  $A \subset X \times Y$ . Since  $p_X$  is  $\theta$ -continuous, by Corollary 2.10.1 [3],  $p_X([A]_\theta) \subset [p_X(A)]_\theta$ . Therefore,  $p_X$  is a almost closed map. Again,  $p_X^{-1}(x)$  is an  $H$ -set in the almost regular space  $X \times Y$ . So,  $p_X^{-1}(x)$  is  $\theta$ -closed. Now, as  $\theta$ -bd  $p_X^{-1}(x)$  is a  $\theta$ -closed subset of the  $H$ -set  $p_X^{-1}(x)$ , then by result 1.15,  $\theta$ -bd  $p_X^{-1}(x)$  is an  $H$ -set in the almost regular space  $X \times Y$  and hence is  $\theta$ -rigid so  $p_X$  is a  $\theta$ -bd perfect mapping. Since  $X \times Y$  is  $\theta J$  (by Theorem 2.16) then by result 1.20,  $X$  is  $\theta J$ . Because of  $X$  is locally connected,  $X$  is a  $gH$ -closed space by Theorem 3.7.

**Remark 4.6.** In Example 2.4, we have seen the product space  $(R^n, \tau^n = \tau \times \tau \times \dots \times \tau)$  where  $\tau$  is the countable complement extension topology of the real line with usual topology  $(R, \mathcal{U})$ , is  $gH$ -closed but  $(R, \tau)$  is not so. We now give some sufficient conditions so that the product of two spaces is  $gH$ -closed.

**Theorem 4.7.** *If the spaces  $X$  and  $Y$  satisfy any one of the following conditions then  $X \times Y$  is  $gH$ -closed.*

- (i)  $X$  and  $Y$  are connected non  $H$ -closed.
- (ii)  $X$  and  $Y$  are  $H$ -closed.
- (iii)  $X$  is  $gH$ -closed and  $Y$  is connected  $H$ -closed (both  $X$  and  $Y$  are almost regular).
- (iv)  $X$  and  $Y$  are connected  $gH$ -closed spaces.
- (v)  $X$  is connected, non  $H$ -closed  $gH$ -closed space and  $Y$  is connected (both  $X$  and  $Y$  are almost regular).

**Proof.**

- (i) Follows from Theorem 4.1.
- (ii) By proposition 4.8L [12],  $X \times Y$  is  $H$ -closed and hence is  $gH$ -closed, by Remark 2.2.
- (iii) Follows from Theorem 4.5, (a) $\Rightarrow$  (b).
- (iv) If  $X$  or  $Y$  is  $H$ -closed, this follows (iii). If  $X$  and  $Y$  are both non  $H$ -closed, then by Theorem 4.1,  $X \times Y$  is  $gH$ -closed.
- (v) If  $Y$  is  $H$ -closed, then proof follows from (iii). If  $Y$  is not  $H$ -closed, then the proof follows from Theorem 4.1.
